Acknowledgements

Before starting this report, I would like to thank my internship mentor for his support and the time he dedicated to training me and guiding me throughout this internship.

I also would like to thank all the staff members of the PETR who welcomed me into this organization with kindness and professionalism.

Finally, I would like to express my special thanks to the people with whom I regularly shared car rides, whether they were members of the organization or not.

Introduction

For this end of study internship at Epitech, from March to September 2026, I got accepted by the PETR du pays de Bray as a geomatics intern under the supervision of Mr. Rémy Fontaine, project manager of the CRTE/OTTEC.

The PETR du Pays de Bray

In this section you will learn about the structure of the PETR du Pays de Bray.

Background

The PETR (Territorial and Rural Balance Pole) of the Pays de Bray is a public structure that was created in 1976 under the name ACTPB (Cultural and Tourist Association of the Pays de Bray). It later became a SMAD (Planning and Development Syndicate) in 2004, before becoming a PETR in 2014.

Today, the PETR of the Pays de Bray brings together nearly 60,000 inhabitants across 114 municipalities, grouped into three inter-municipal communities: Londinières, Bray-Eawy, and 4 Rivières en Bray, covering a territory of approximately 1,300 km².

The PETR is located in the Normandy region, in the eastern part of the Seine-Maritime department, its territory is mostly rural.

Governance

The syndical committee is composed of elected representatives delegated by the inter-municipal communities. The distribution of seats takes into account the population size of each community.

The committee meets at least once every quarter, upon the initiative of its President, in order to discuss and vote on projects.

The syndical committee of the Pays de Bray includes 39 elected members and an equal number of substitutes.

Departments

The PETR is divided into two main departments: the Territorial Initiative Support Department (SIT) and the Territorial Structure and Analysis Department (SAT).

The SIT is organized into two divisions. The first one, dedicated to sustainable development, includes programs such as Natura 2000, MAEC (Agri-Environmental and Climate Measures), and the "Hedgerow Pact". The second one, called the LEADER division, focuses on supporting and funding local projects through European funds.

The SAT is also composed of two divisions. The first one, the ADS division, is responsible for urban planning for 54 municipalities. The second one, the ADT division, manages several strategic tools and programs, including the SCOT (Territorial Coherence Scheme), the OTTEC (Territorial Observatory for Ecological and Climate Transition), and the CRTE (Recovery and Ecological Transition Contract).

Organizational Chart 2026

Figure 1: Organizational Chart of the PETR du Pays de Bray

Technical Terms and Concepts

This section introduces some technical terms and concepts that are related to my internship and are used in this report. It is intended to help readers who may not be familiar with the technologies and domains involved in the projects described.

Geomatics terms

In this section I will explain the Geomatics terms that are related to my internship. Geomatics is the fields that merge geography with computer science, it can be used for many subjects like urban planning, spatial analysis, risk management, social research and much more.

Let me now explain the OTTEC which is an acronym that can be translated as the Territorial Observatory for Ecological and Climate Transition. It's a tool mostly made of interactive maps about a lot of subject to help visualize the data of the PETR du Pays de Bray. Its goal is to provide information to the elected representatives to help them decide if a project is relevant or not regarding multiple sourced data. The OTTEC is built using a geomatics software called QGIS.

QGIS is an open-source Geographic Information System (GIS) used to create, edit, analyze, and visualize geographical data. It allows the users to design maps using multiple data sources to calculate statistics and run spatial operations.

Yet, QGIS alone doesn't do everything for the OTTEC. To fully build interactive maps and make them accessible for every elected representative, for that an additional plugin must be wired to QGIS which is called QGIS2OGIS in our case. QGIS2OGIS is a QGIS plugin that exports geographical projects as interactive web maps. The generated website allows users to explore geographical data directly from a web browser.

An interactive map is a web-based map that allows users to navigate, zoom, search, and interact with geographical information.

The geographical data are often mentioned as layers. A layer groups one type of geographical data.

Information technology terms

Python is a high-level programming language widely used for software development, automation, data processing, and desktop applications.

Regex is short for regular expression, they define pattern for text to search in a file or in a portion of a file.

"PyInstaller" is a tool used to transform Python applications into Windows executables.

"QT" and "tkinter" are graphical user interface frameworks for desktop application.

VBA is the acronym of Visual Basic for Applications, it's a scripting language integrated into Microsoft Excel.

Excel Macros, often mentioned to as macros in this report are the code developed using VBA.

HTML (HyperText Markup Language) is the most basic language to develop a website.

CSS (Cascading Style Sheets) is a language to describe how elements should be rendered for the website.

JS (JavaScript) is a programming language mostly used to make websites dynamic.

Part 1

Project handover for a new team member

In this part, I will describe all the projects that I worked on and that a new team member may work on in the future. All the project that I worked on are available on the shared drive in a folder named “2026_STAGE_DEVELOPPEMENT”.

1.1 OTTEC’s MISSION

The OTTEC department makes interactive map to show data about the PETR for the elected representative to guide them with better understanding about this territory. To update the interactive map was a long and manual process, so they decided to hire someone to create a tool to update the interactive maps better and faster. So, I was hired for this internship with the goal to develop software to modify exported maps that I called the Project Editor (EDP).

A first step in this internship was to understand the way interactive maps worked and were created, this was started by updating an interactive map manually by translating its buttons.

Figure 2: Example of an interactive map showing the limits of the Intercommunal cooperation public Establishment (EPCI) of the PETR.

In this figure you can see what an interactive map can look like, in the left part you have the sidebar with tabs that open with text or button to perform actions like print, still on the left you have the map control buttons to zoom, measure, etc. and below the scale of the map. On the right part you have on top more buttons followed by the layers of the map that are directly exported from QGIS. And the main part of the interactive map the interactive map where the layers show one on top of the other.

1.1.1 EDP

The EDP is a desktop application designed to edit interactive maps generated from QGIS export, it was in the first place created to have an easier way to update the interactive map and not do it manually each time we needed to update an interactive map which was too time consuming and complex.

The goal of this software was initially to add a new layer to an interactive map, to do that we need a file that contains the data of the layer, for example a file that lists all the wells with their position, depth and date of construction, we also need a file that describe how each well will be represented on the map and we also need a picture to put in the legend.

The approach I chose for it to work is for the user to create a new export of only the new layer to have all those files and then the software imports the files into the existing project. In accordance to the user of the app I implemented new functions, one to create groups of layer and nested groups, a function to remove a layer and a function to rename a layer or a group. Once all the functionalities have been implemented, I created a menu to launch multiple functionalities. That menu is composed of a button to select a project, the path of the project, the logo and title if found and the list of possible actions.

The list of possible actions is firstly the modification that are listed previously all under one interface, in a second place I have coded a functionality to deactivate or activate certain possibility for the interactive map, for example the user of the EDP can choose to deactivate the full-screen button or deactivate the button to show the mini-map.

Then the application has a functionality to change the content of the sidebar and the side panel, the user can change the order of the sidebar items, change their icons and title.

Next, we can find a button to change the style of the interactive map, in particular the position of the button for example if we deactivate a button, we need this functionality to change the position of the button under it to replace the deactivated button.

Another feature is to change the attribution information of a specific layer or of the map in global, next to that there is a button to change the extent of the map. There is also a functionality to change the bookmark of the map.

Then there is a big piece, this button does a lot of things and has the goal to transform a new export into a model that was defined to be shown to the public.

Finally, there are buttons to translate the project, to add a help popup to the start of the page, to add an assistant in the sidebar, to update a component, to add an intersection of layers and to add a better search.

All these features answered the needs of my internship mentor and were presented and tested by him all along this project.

Figure 3: Screenshot of the EDP main page.

This project is developed in Python, I used the “tkinter” library for the graphical interface and I used the “pyinstaller” to create an .exe file from the Python code. For most of the functionality I used regex. What I call an interactive map is the result of an QGIS export using the “QGIS2OGIS” ’s plugin. The structure of an interactive map is in the first place an “index.html” that is the entry point of the web page, then we have a style folder that groups all the layers style and legend, it has a resources folder with the script for the interactive map and all the dependencies and libraries, it also has a layers folder with all the layer data and an empty images folder.

When updating this application because of a new version of the plugin you need to be careful of the regex that can change between version, for example for the sidebar it has changed from “sidebar start” to “sidebar v2 start” during my internship.

Figure 4: Folder structure of the code.

In each folder you will find multiple files, in the editors’ subfolder you have one feature by folder except the simple folder that groups smaller feature with each one its own file. In the transform folder each feature is in its own file. The layer and sidebar groups the operation

that change to the layers or the sidebar of the project. The utils folder groups shared functions that are used in multiple features. And finally, the core folder has the entry point of the application with the menu to choose which feature to execute. This project has a total of 37 Python files with approximately 25 000 lines.

I also used “Sphinx” to create a documentation of the project that describes each function so that it will be easier for someone who doesn’t know all the functions of the project to understand the project and to fix a bug if some bugs are detected in the future, you can find it on the shared drive.

In this project I encountered multiple difficulties, the first one was to understand the exported map and layers, they can be small changes between each layer and I needed to make sure the regular expression grabbed all the layers and after changes saved the layer to be correct and valid to be shown on the map. A second difficulty that I encountered when updating the plugins to export the interactive map was to make sure that the compatibility with the old version still works and the new change doesn’t break the regular expression. And finally, I encountered a trouble to implement the 3d button that add the possibility to view the map in 3d, to create the 3d map because there are not free sources for it and secondly to synchronize the 2d and 3d map.

This project was completed faster than my internship mentor planned that I was given other missions. With each mission, my internship mentor let me work with more autonomy.

1.1.2 Atlas

Another mission that was related to the OTTEC was to create an electoral atlas, the application lets the user choose a commune and show the elected representatives of this commune and the local council community. The main page of this web application shows also the elected representative for the PETR, the departmental and the regional council.

The application relies on CSV files, whenever local elections take place or elected officials resign or are replaced, these files must be updated to keep the application accurate. When updating the CSV file, you may need to add the title for the EPCI president and vice president.

When a commune is selected the application is divided in 3. In the right part there is the interactive map that show the PETR and let the user select a commune. In the top left part, there is an interactive map that show the commune selected and has information about its townhall. And, on the bottom left part, there are the elected representative information like who the mayor is and who’s in the municipal council. You can see what it looks like when the Saint-Saire commune is selected just below.

Figure 5: Page of the Atlas displaying the elected representative for the selected commune. (The user interface is in French because the application is intended for local government employees and residents.)

The difficulties of this project were in the first place to know which data of the CSV files to get and how to get the right filter to select all the concerned elected representative. Another difficulty was to select the right layer to show on the maps.

1.1.3 OTTEC Dashboard

Another mission was to create a dashboard that brings together multiple datasets related to the PETR area, it was regrouped in 3 big categories, population, economic and territorial categories. This mission goal was to help and speed up the process of territorial diagnosis which is a legal obligation of the public organization like the PETR for all their projects. The diagnosis is a process to analyses scattered data around multiple datasets and data sources, which often is raw data that need formatting and calculating to have a territorial diagnosis. So, this is a long and costly process that takes a year on average. This mission solves this problem and allows with a single web page to see all collected data formatted with charts and data. The web page will also be made available to the elected representative to serve the OTTEC's mission to make data available for local representative. And with a PDF export to see all the data distributed by categories, that will allow for the future territorial diagnosis to save time and money.

The data is mainly retrieved from Melodi the open data API provided by INSEE (The National Institute of Statistics and Economic Studies collects), today they have 79 datasets publicly available with a spatial resolution that's interesting for the PETR's area. We also use other publicly available data from other API, the Georisks (www.georisques.gouv.fr/api/) that list all the risk for a commune such as inundation, volcanic risk and many other. Another one used

is the API from Ecolab which has a lot of data about ecological transformation but it has zero to none documentation about the metrics of the data.

This project refreshes its data automatically after a certain time, that means that If INSEE update their dataset the application will be updated with the new data, it also means that we are reliant on the INSEE's API and if the application doesn't update, you'll need to look at it, if they have changed their working process. When they update their dataset, the dataset will be deleted and for a small period of time up to a day it will not appear in the API.

This project has 2 versions. One that show the data of the 3 EPCI (Intercommunal cooperation public Establishment) of the PETR and you can choose to activate or deactivate each one. The second version focuses on a single commune, allowing users to display detailed indicators for the selected municipality.

The difficulties of this project were, in the first place to understand how the data were stored and what was stored where. Another difficulty was to understand if it's the app that doesn't make the right connection on the APIs or if the API were out of service or the dataset required was being updated or just removed.

Figure 6: Screenshot of the OTTEC dashboard on the housing part on the EPCI view.

In this screen shot you can see the up part of the housing tab, on the left you can see the tabs that groups the data by categories. And on each category, you have multiple charts and data visualization with for each the dataset which the data came from.

1.2 Other missions

In this part, I will tell you about project that I worked on that are not part of the OTTEC. These missions were given to me to develop solutions to answer needs or to simplify existing solutions.

1.2.1 BrayIA

One of the projects that I have worked on was “BrayIA” which was a project to have a conversational model that could help town hall secretaries and citizens in the Pays de Bray’s area with administrative questions, the goal was to have an AI that has a focus on the Pays de Bray to answer the question.

I first tested this idea with Ollama, a self-hosted tool that runs open-source large language models such as Mistral or Qwen. Two issues came up, firstly my personal computer's hardware was too limited to run larger, more reliable models, and even after asking the PETR’s supplier to quote a dedicated server, the cost was well above our budget. Secondly, smaller models that do run locally also proved less reliable, often giving inconsistent or inaccurate answers.

Given these constraints, my recommendation was to rely on an existing AI service rather than self-hosting, which would guarantee better answer quality without the upfront hardware cost.

Figure 7: prototype of the web page for BrayIA.

On this figure you can see the test web page for BrayIA where the user could ask a question and will get an answer.

1.2.2 Mediatech

During this internship I also worked on a photo and video tagger that scans a folder and has the possibility to add tags to the media scanned. The interface is divided into 3 parts. The left side has on top the folder tree structure and below a tree structure of the tags put on top of the pictures and videos. In the center of the graphical interface we can find in the top part a bar with filter like the localization of the media or we can filter to show only video, below that

we can find the pictures and videos that meets the selected tags and filter. On the right we can find if a media is selected the metadata of the file, the list of tags of that image and a button to add a tag to the selected image. This project was developed in Python and use the “QT” library for the graphical part, this library was chosen for its look more beautiful.

Figure 8: main process of the app, in pink the process to get the data and metadata of a folder and in green the process to add a tag to a media.

In this figure you can see 2 process, in the top the process to scan a folder that creates a database file for the folder selected and scan all the subfolders and media to create an entry in the database with its data and metadata and if a folder is rescanned it will update the database by removing the removed media and creating new entries for the new media without changing the already existing medias. On the bottom is the process to add a tag to a media, the application opens and loads all the data of the last opened folder, and show all the tags and media, then the user selects a media and choose a tag to add, then the application automatically saves the change in the database.

Figure 9: “Mediatech.exe” with a picture selected

As you can see in this figure you have on the left part of the application all the folders and all the tags, in the center you have all the medias that meets the selected tags in this example only the tag nature is selected, in the right part you have the information of the selected picture with its metadata like size, name, path, etc., and its tags and below a button to add tags to the selected picture.

The difficulty of this project was to get the videos thumbnails to generate. One of the difficulties encountered was to have the tags synchronized between users.

This project has been presented to all team members that use medias in their work which is 7 people.

This project has a total of 20 Python files for a bit more than 7 500 lines distributed between the backend and the frontend.

1.2.3 OBU

One of the projects was to develop automation for the OBU (single budgeting object). I chose to use Excel VBA (Visual Basic for Applications) to automate the already existing tool which is an Excel file. After some time to understand the file structure, which is separated in multiple sheets for each department to plan the budget, with a sheet for the accounting of each expense and each income. The first step was to automate the manual entry that take place at 2 places in the document by the accountant, I developed in the first place a script that allowed the accountant to make an entry and rebound it at the needed place, then in a second place I let the accountant enter an entire statement that she can copy from her software and then repeat the previous process for those entries.

In this excel file, I also created other scripts to report all the error shown in the sheets, and a script to create a new section that respect the M57 which is an accounting's nomenclatures for communal and intercommunal collectivity. This script works by finding a model and insert it in the user's selected sheets with the name and the code that the user entered, and after finding the right place to insert the new article, it updates the formula and the article is inserted.

The difficulty of this project was to understand the structure of the excel files and how the accounting works and specifically the accounting for the local public finances.

Then this project evolved, in accordance with the director and the induced complexity. It evolved by becoming a Python application that regroup all the functionalities wanted by the director and the deputy director. I implemented the already existing functionalities in the excel file and in the macros and implemented the requested functionalities by the deputy director and the director like a new way to see the organizational chart and to plan the budget and to better see the different fundings that was planned, all that in this Python application. Like the EDP this application use the "tkinter" library for the graphical interface and the "pyinstaller" library to create an .exe file from the Python code.

Figure 10: OBU's first tab that let the accountant enter new entries in the tools.

In this figure you can see all the tab of the application, a tab can group multiple functionalities. The first two tab are to keep track of the expense and the revenue of the PETR du Pays de Bray. The next two are global and by departments overall of the expenses and revenues. There is next a tab to create the budget. We next have 2 tabs that allows to manage the organizational chart and wages planning. The we have a tab that list all the M57 section where the user can update already existing section if the nomenclature changes. Finally we have the last 3 tabs, in order let the user export data in different format, then the settings of the application and to finish an help tab that list all tab and how the user can interact with each one.

1.2.4 Educational game

One of my missions was also to adapt interactive PowerPoint that were small game or story to have an activity that school teachers can raise awareness for ecological good practice. There were two PowerPoint presentations to transform into a website, the first one was started by my internship supervisor and finalized by me, and the second one has been done by me entirely, those games were made using html, CSS and mostly JavaScript. You can find in both game a file that contains all the question or stories, and a file that does all the game logic.

The goal was to transform heavy PowerPoint that had to be downloaded to a lighter website that can be accessed by anyone that has an internet connection.

The first game is called "Aux quatre coins de la nature", it's divided in 4 themes. They are in order, the forest, the field and meadow, the hedge, the aquatic environments. Each theme has multiple question to make the user discover different animals and how to recognize them. For

example, in one type of question, four different animal are shown and the player has to identify the correct answer. The game asks “Where is the crow?” and the player must click on the image of the crow. Then the game tells the player if he was right or wrong. Another type of question consists in recognizing an animal by its sound.

The second game regroups 4 circumstances where the user can choose between 2 choice that make the story progress in different way. The story give explanation for the user choice to help them understand the good practice and small gesture to help the environment. You have a JavaScript file for each story which list all the choices of the story, if you want to change a story it's here that you need to look, you also have a file that handle all the rendering depending of the story data.

The games can be accessed by these links, <https://www.paysdebray.org/animations/jeu-web-aux-quatre-coins-de-la-nature> and <https://www.paysdebray.org/animations/lesaventuriersduquotidien>

The difficulty for this project was to understand the already existing work, and to correct the images for the first educational game.

Part 2
Self-assessment

As my internship comes to an end, I will reflect on my strengths that helped me during this experience and I will also do the same with the areas that I'm aware of and I will continue to improve.

2.1 Strength

To start this section, I will introduce 3 strengths that were useful and helped me during all this internship.

2.1.1 Adaptability

During this internship I made use of adaptability to work on the various projects that I have worked on. I have worked on multiple projects with different technologies that I knew or not. For example, I knew the Python language but I didn't know VBA, so I adapted and learned in order to automate Excel process. Even for languages that I knew such as HTML and JavaScript, I still learned new thing to adapt and use interactive map. Before my internship I never heard of QGIS, so I discovered it and learned what I needed to know for my missions.

2.1.2 Autonomy

One of my strengths was my autonomy, that allowed me to work on multiples projects at the same time, to propose solutions to problem that were given to me and also let me explore multiple possible solutions. For example, in the dashboard project I did all of the research of where the data was located, on how to get it and how to show it to the user and worked on it in autonomy and showing the progress to my internship mentor who gave me feedback to upgrade the application. With the atlas project I started from a sketch of my internship mentor and were to find the data then I worked on the application in autonomy.

2.1.3 Problem-solving

Another strength of mine was my problem-solving skill that let me overcome the difficulties encountered during my internship. It also made me able to be proactive in solving problems that was given to me to solve. For example, in the EDP project after trying multiple methods to merge layers, the easiest way and more secure way was chosen to implement it.

2.2 Areas for Improvement

To continue this self-assessment part, I will describe the areas that I need to work on and continue to improve.

2.2.1 Verbal communication

During this internship, I realized that I sometimes spend too much time trying to solve a problem on my own before asking for advice. Although this allows me to improve my problem-solving skills, I have learned that discussing a blocker earlier can save time and lead to better solutions. I therefore want to improve my communication with colleagues by sharing my progress and asking for feedback more regularly.

2.2.2 Task prioritization

Working on several projects at the same time taught me the importance of prioritizing tasks. I sometimes focused too much time on perfecting a feature before moving on to the next one. In the future, I want to improve my ability to balance quality with deadlines and business priorities.

2.2.3 Public speaking

During this internship, I realized that public speaking is one of the skills I still need to improve. When presenting my work to a group, I sometimes hesitate or stammer during my explanations. Although my presentations remained understandable, I believe that becoming more confident when speaking in front of an audience will allow me to communicate my ideas more clearly and professionally.

Part 3
Dream project proposal

As my internship comes to an end, I would like to present you the project that I dream about and why I want to work on it.

3.1 Context

The PETR currently relies on an external QGIS plugin developed by an Italian team to generate interactive maps. Although this plugin meets our current needs, it also creates a dependency on a third-party project. If its development slows down or is discontinued, maintaining and improving our interactive maps could become difficult and costly. Furthermore, any major update to the plugin may require modifications to our internal tools, such as the EDP application and our interactive maps.

3.2 Project

My dream project is to develop our own version of this plugin so that we are independent from the Italian one. The project will have French as main language. From what I learn during this internship I will be able to implement functionalities specific to the PETR. It will be tailored for the use and have better functionalities.

The project will be started from scratch to make it faster by focusing on the functionalities that the PETR needs and by starting from scratch this project will avoid legacy code from the old plugins. The project will start with 2 weeks to list all the functionality needed. Then in the next 2 months, we can have the base of the new plugin, then will start a week period of functional testing, then after another week of fixing the bug will start a 3 months period to develop the needed functionalities. Finally will be a month to test and recreate all the old interactive map with the new plugin.

For this project, the new functionalities that are not in the old plugins would be in the first place. The update of already existing map in QGIS directly this would be an option of the plugin to update only the data without recreating all the app. Also similar to the first one that only change the data we could add a feature to add a layer, it will regenerate only the part related to the layers and not change the rest of the page, this feature will be followed by the operation on the layers that exist in the EDP like removing a layer, renaming a layer, etc.

Another interesting feature would be the customization of the interactive maps, it will be interesting to have personalization of colors with theme already made or to let the user choose the colors of their interactive maps.

3.3 Company's interest

For the PETR this project will make development of interactive map more flexible and will make it possible to sell the plugin for a French audience. It also means that we will not rely on external plugin and will be able to develop custom feature.

By giving me this project you will have a competent employee that knows the PETR interactive map specificity and have worked on the interactive map and seen how the old plugin work.
